

About PreTeXt

Richard Koch

July 22, 2019

1 Remembrances

TeXShop was started in May of 2000, when OS X was still in beta. The first web release was in July of that year. Recently I recovered sources for that release and discovered that they still compile on modern versions of OS X. Such a modern copy is available on the TeXShop web page.

Interest picked up with the release of OS X on March 24, 2001. Sometime after that I was invited by Wendy McKay to speak at the TeX User Group Conference at the University of Delaware in August of 2001. Wendy McKay worked with Jerry Marsden at Cal Tech; both were Macintosh fans. MacTeX is Wendy's idea.

I remember just one thing about the talk. To show how easy it was to use TeX on OS X, I installed it during the talk. The Finder crashed in the middle and had to be restarted. After the talk, an audience member came up to me and said "I'm not interested in TeXShop, but I'm very impressed that you could restart the Finder without rebooting the system!"

2 The TeX User Group

In 2001, I had a very distorted notion of TUG. I learned that the central offices of TUG are in Portland, Oregon, and imagined that they covered one floor of a large downtown skyscraper, with many employees handling the journal *Tugboat*, the DVD's, etc. The executive directory of TUG is Robin Laakso, and actually the TUG office is one room in her house and those many employees are Robin, Robin, and Robin.

Wendy offered to pay my conference fee and travel to Delaware, and I expected a large conference of perhaps 2000 TeX users. But when I got to Delaware, I discovered that there were around 50 people, most of them speaking at the conference. All had paid their own way. So I sheepishly repaid TUG the conference and travel amounts (at least, that's how I remember it).

Since Delaware, I've gone to many TUG conferences and learned a lot. Some talks are by beginners explaining what it is like to start using TeX. One such speaker's advice was "install everything right away, so packages and examples from books just work." That is why MacTeX installs the full TeX Live. Other talks were technical by the authors of XeTeX and LuaTeX. One of the most useful talks was on Beamer by Andrew Mertz and William Slough; I'd listen to any talk those two give. After that talk, UO faculty sometimes asked me how to produce slides and I noticed that this question usually came the day before their plane left for Budapest and two days before their talk. I'd always suggested Beamer and the Mertz and Slough article and never had a dissatisfied customer.

3 Unusual Talks

But mixed in with these standard talks were some unusual topics I had a hard time understanding. Every conference seemed to have a couple of talks on xml (Extended Markup Language). The speakers were often able to type xml code at a ferocious rate, and they would indent to show the structure of the code, and soon the indentation level seemed to be several pages wide, particularly if MathML was included.

I gradually learned that xml code can be edited by computer programs, while TeX code requires hand manipulation. For this reason, many publishers require submission in xml. It seemed that researchers wanted to manipulate TeX for interactive output and make other advancements and each required xml. But even after many talks, I was unable to understand many details, and I gradually ignored xml.

4 Pessimistic Talks

From time to time, a famous TeX expert's talk would be pessimistic, concluding that TeX had very little future. Sometimes the conclusion was that mathematicians would still input equations using TeX syntax, but the structure of documents would be described by an entirely new language.

Why the pessimism? Some of my friends concluded "they are just getting old". But I began to notice that many of these experts were working in the Open University movement in England, teaching OnLine courses which required material on the web and highly interactive content. Instead of homework graders, homework answers were often checked immediately by machine; this was required by the large number of students, but also made for a more useful homework experience. Interactive graphs and demonstrations were necessary to hold the interest of students distracted by others in their home. All of these things are difficult to do with ordinary TeX.

I'm retired from teaching at the University of Oregon, but I noticed my colleagues dealing with the same issues locally. So the interest in TeX extensions seemed to have a genuine

cause. But practical solutions were another matter.

5 TUG 2014

The national meeting of TUG in 2014 was in Portland, Oregon. At last, a conference I could drive to! Among the talks on the first day was Robert Beezer’s talk on Mathbook XML. This is the old name of PreTeXt, and as an example Beezer described conversion from LaTeX to PreTeXt of a book by my former Phd student Tom Judson. The talk was clear and vivid, but I kept thinking “hey, I know this guy Judson.” After the talk I discovered that Beezer and Judson met while bicycling in France, and that is what I most remember. I’m ashamed that I didn’t pay closer attention.

6 Dev Sinha

In 2017, I was at the University for a groundbreaking ceremony for a new building. The ceremony had donors wearing suits and administrators, and I felt out of place until I recognized another mathematician, Dev Sinha. We left so I could hear a lecture on topology Sinha was to give, and on the way he asked what I knew about xml. I told him that mainly it takes a long time to type. Sinha disagreed, and told me that he was writing course notes in xml using a system from the University of Puget Sound, and he gave me a web address.

That night I went to the web site, and after a few minutes I thought “wait a minute; I know this project.” It was the PreTeX page, and among the names on the page were Robert Beezer and Tom Judson. Then I noticed that the xml code was for document structure, but mathematics was still written using LaTeX commands. Finally I noticed that several other people I knew from the University of Oregon were involved in the project.

But what really struck me was the down-to-earth nature of PreTeXt. The author seemed to be interested in solving the problems teachers face in the modern world, not in ideas which might bear fruit in the future. PreTeXt used the best available technology. Thus xml for structure, but Latex for math. To get the Latex on the web, it uses MathJax, a technology promoted by the American Mathematical Society which has become a standard for math on the web.

So, sometime in 2018, I added PreTeXt engines to TeXShop. But PreTeXt is evolving rapidly, and those engines are now out of date.

7 PCC Climb Center in Portland

In June, 2019, I spent a day attending a session at a week long conference on PreTeXt at the PCC Climb Center in Portland. Several people there suggested changes in the TeXShop PreTeXt Engine, and these changes are described in the next section. They also suggested additional features in TeXShop which would improve it as a PreTeXt front end. Those are all now in the program. Thanks to Thomas Judson, Kent Morrison, Dave Resoff, and Rob Beezer for these suggestions.

It is now the middle of July, 2019, and I'm about to release the version of TeXShop that really supports PreTeXt. Readers who want to use PreTeXt, or at least try it, should read a second document in `~/Library/TeXShop/Engines/Inactive/PreTeXt`, which covers setting up PreTeXt and those features in TeXShop which support it.

8 Conclusion
